## DEVICE FOR THE TREATMENT OF HYDROCEPHALUS

The present invention relates to a cerebrospinal fluid shunt system for shunting cerebrospinal fluid from the brain ventricles to sinus sagittalis.

## 5 GENERAL BACKGROUND

Cerebrospinal fluid is formed in the ventricular system irrespective of the intracranial pressure (ICP). The formation rate is constant, with a range of 0.3-0.4 ml/min. (Børgeesen and Gjerris 1987). Hydrocephalus, i.e. a pathological increase in the amount of intracranially located cerebrospinal fluid, arise when the outflow of the cerebrospinal fluid is obstructed leading to an increase in the intracranial pressure and in the amount of intracranially located cerebrospinal fluid. The obstruction may be localized in the aqueduct or the IV ventricle or in the normal resorption sites in villi arachnoidales in connection with the sagittal sinus. Pathoanatomically, hydrocephalus is divided in communicating or non-communicating hydrocephalus dependent whether there is passage between the ventricular system and sinus sagittalis or not. Communicating hydrocephalus, which is generally caused by obstruction located in the villi arachnoidales for example due to fibrosis formed in response to bleeding in the liquor, is the most common form of hydrocephalus.

25 The treatment of hydrocephalus aims at reducing the intracranial pressure to normal, physiological values and thereby also reducing the amount of cerebrospinal fluid towards normal, physiological values. This is obtained by deducting cerebrospinal fluid (CSF) from the ventricular system to another resorption site, bypassing the pathological obstruction by use of a CSF shunt. The most suitable diversion sites for CSF have been found to be the right atrium of the heart and the peritoneal cavity. Valves have been designed to hinder retrograde flow in the drainage system which could occur due to pressure differences between the intracranial

cavity and the resorption site, e.g. in connection with increased chest and/or abdominal pressure in connection with e.g cough or defecation.

Until the last 6 years the CSF shunts have been based on the 5 principle of maintaining a constant ICP regardless of the flow-rate of CSF. The CSF shunts have been constructed to cut off CSF-flow when the differential pressure between the inlet and the outlet of the CSF shunt was reduced to a predestined level, called the opening pressure of the shunt. This has 10 been necessary in order to maintain a basal ICP due to the use of an unphysiological resorption sites located outside the intracranial cavity. Example of a such ICP shunt is shown in US 4,904,236 which is a fluid flow control device for controlling the flow of fluid from one region of the body to 15 be drained to another region.

Clinical experience has proven that this principle of shunting is not an ideal solution. Sudden rises of the ICP, e.g. due to change of position, physical exercise, or pathological pressure waves result in excessive CSF drainage. This so-called hyperdrainage leads to subnormal ICP for shorter or longer periods of time. Several reports in the literature 20 (Aschoff et al., 1995) point at problems due to this hyperdrainage, and especially the pronounced narrowing of the ventricles has been pointed out to be the main factor leading 25 to malfunctioning of the implanted shunting device. The reason is that the ventricular walls may collapse around the ventricular CSF shunt device, and particles (cells, debris) may intrude into the shunt device.

This has led to introduction of multiple designs of drains to 30 be used in the ventricular cavity. An effect of these different drain designs on the complication rates of shunts has not been proven.

In the recent years CSF shunt devices have been introduced which aim at regulating the flow rate of CSF, see e.g. US

4,781,673 which describes a brain ventricle shunt system with flowrate switching means.

An alternative flow regulating mechanism of the Orbis Sigma shunt results in partial closure of the shunt at increases in 5 the differential pressure above 10 mm Hg, and in reopening of the shunt when the differential pressure exceeds 35 mm Hg. It has been shown that this type of shunt indeed leads to a reduction of the complication rate of the system. Another shunt system, The Pudenz Delta valve, also hinders excessive 10 CSF outflow at higher pressure levels. US 4,605,395 is an example of a shunt device comprising a nonlinear hydraulic filter valve which closes in the event of large changes in flow rate.

Still, the above CSF shunt systems drain the CSF to a resorp- 15 tion site that is far from normal and to a site where the pressure difference over the shunt may differ substantially from the normal, physiological pressure ranges.

Occasional reports in the literature have described the use 20 of ventriculo-superior sagittal shunts for the treatment of hydrocephalus (Hash et al., 1979 and Wen, 1981). In the article by Hash et al. it is concluded that the described technique wherein a low-low or extra-low pressure one way valve is used may be suitable for patients with high pressure hydrocephalus and of particular value in very ill or debili- 25 tated patients because of the rapidity with which it can be performed under local analgesia whereas its use in normal or low pressure hydrocephalus must still be evaluated. This article is followed by a comment by the editor that there are a multitude of remaining critical questions. One of the 30 problems not addressed in this study is overdrainage due to the fact that the used valve is not flow-restricting.

Wen reports the treatment of fifty-two children with hydrocephalus with ventriculo-superior sagittal sinus shunts by use of a modified Pudenz tube. In this tube there is provided

slits which provide an opening pressure of about 6 mm Hg. No clear conclusion can be drawn from this report except that shunting to the sagittal sinus does not inherit serious complications.

5

EP 066 685 describes a drain comprising a bundle of one or more microtubules, each being about 0.44 mm in diameter for controlling hydrocephalus comprising a plurality of pliable microtubular members for conducting cerebrospinal fluid from 10 the cerebral ventricle to selected areas of the human body, e.g. to the subarachnoid space. Essentially, this patent relates to a draining system aiming at avoiding obstruction due to clotting of the draining system and is not flow-regulating.

## 15 SUMMARY OF THE INVENTION

The device for treatment of hydrocephalus of the invention leads the CSF from the ventricles to the sagittal sinus beneath the sagittal suture. The present invention thus provides a CSF shunt system that treats the hydrocephalus by 20 bypassing the pathological obstruction, but diverts the CSF into its normal resorption site, and the pressure difference over the CSF shunt system is similar to the physiological pressure differences between the ventricles and the resorption site, thus regulating the CSF flow to be within the 25 normal range and avoiding complications due to hyper drainage. Where appropriate, the present invention also relates to a method of treating hydrocephalus by use of the cerebrospinal fluid shunt system of the invention.

## LEGENDS TO FIGURES

30 Fig. 1 shows a cerebrospinal fluid shunt according to an embodiment comprising an antechamber, a flow regulator, and a check valve connected in series.

Fig. 2 is a side view of a cerebrospinal fluid shunt according to a preferred embodiment in which the flow regulator means is divided in two parts with the check valve inbetween them.

5 Fig. 3 is a top view of the same cerebrospinal fluid shunt.

Fig. 4 shows three cross-sections through the check valve with the ball of the check valve.

10 Fig. 5 shows the cerebrospinal fluid shunt with an antechamber, a unidirectional check valve and a flow regulating tube, top view.

Fig. 6 shows the cerebrospinal fluid shunt in a lateral view.

Fig. 7 shows the cerebrospinal fluid shunt in a three-dimensional view.

15 Fig. 8 is a frontal section through sinus sagittalis superior.

Fig. 9 is a sagittal section through sinus sagittalis.

Fig. 10 shows the influence of the length on the radius given a resistance to outflow at A. 8 mm Hg/ml/min, B. 10 mm Hg/-  
20 ml/min and C. 12 mm Hg/ml/min. In these particular examples, the differential pressure is 4 mm Hg and the viscosity is 0.0072 dyn\*sec/cm<sup>2</sup>.

#### DETAILED DISCLOSURE OF THE INVENTION

25 In normal conditions the CSF is produced in the choroid plexus in the ventricles. It flows through the ventricles, aqueduct and basal cisterns over the cerebral surface to the arachnoid villi, from where the CSF is absorbed into the sagittal sinus.

From measurements in 333 patients (Børgesen and Gjerris 1987) and 52 normal humans (Albeck, Børgesen et al. (submitted for publication)) it has been possible to establish the relationship between CSF production rate (FR), intracranial pressure 5 (ICP), pressure in the sagittal sinus (Pss) and the resistance to outflow of CSF (Rout):

$$ICP = FR * Rout + P_{ss}$$

The relation between the intracranial pressure and the formation rate is linear, and the production rate measured was 10 found to be 0.3 ml/min. (Børgesen and Gjerris 1989).

The detailed knowledge on CSF-dynamics, obtained in the laboratories at the Department of Neurosurgery, Rigshospitalet, Copenhagen, Denmark, has provided the necessary data which could make it possible to define a CSF shunt system that 15 imitates the normal, physiological drainage of CSF. However, until the present invention, it has not been proposed or contemplated to use this knowledge to design a cerebrospinal fluid shunt system as outlined in the following.

The present invention relates to a cerebrospinal fluid shunt 20 system comprising brain ventricle catheter means for insertion into the brain ventricle so as to drain cerebrospinal fluid from said brain ventricle; sinus sagittalis catheter means for insertion into the sinus sagittalis for feeding said cerebrospinal fluid into sinus sagittalis; shunt main 25 body means connected at one end thereof to said brain ventricle catheter means and at another end thereof to said sinus sagittalis catheter means for providing fluidic communication between said brain ventricle catheter means and said sinus sagittalis catheter means; and tubular flow passage restricting means defined within said shunt main body and fluidically connecting said brain ventricle catheter 30 means and said sinus sagittalis catheter means, said tubular flow passage restricting means defining a system total resis-

tance to flow of 8-12 mm Hg/ml/min. Preferably, the resistance to flow is about 10 mm Hg/ml/min.

Essentially, the tubular flow passage restricting means for fluidically connecting the brain ventricle and the sinus sagittalis could in itself act as a brain ventricle catheter means and a sinus sagittalis catheter means thus making the construction very simple, the only limiting factor being that the device should define a resistance to flow of 8-12 mm Hg/ml/min.

5 10 15 20 25 30

10 Optionally, the cerebrospinal fluid shunt system further comprises check valve means disposed within said shunt main body for preventing said cerebrospinal fluid from flowing back from said sinus sagittalis catheter to said brain ventricle catheter.

15 By designing the shunt to exert a substantially constant resistance to outflow at the normal level, and by using the sagittal sinus as the resorption site, the drainage of CSF is regulated by the normal pressure differences between the production and the resorption sites. Excessive increases of the 20 intracranial pressure are paralleled by increases also in the sagittal sinus, and the CSF outflow through the shunt is impeded by a resistance in the normal range. Hyperdrainage is then totally avoided.

25 The innovation is thus to use the recently defined levels of the normal resistance to CSF outflow and create a resistance to CSF-outflow in the shunt similar to the normal resistance. By using the sagittal sinus as the recipient site, physiological increases of the intracranial pressure will not increase the differential pressure over the shunt. Posture-related changes in the differential pressure as seen in shunts leading the CSF to the right atrium of the heart or to the peritoneal cavity are completely avoided. Overdrainage which is the most frequent reason for shunt failure in conventional shunts is thus also avoided.

Including a check valve such as a ball valve in the shunt will hinder any reflux of blood from the sagittal sinus into the shunt (or the ventricles). The check valve is constructed in such a way that it has substantially no resistance to the 5 CSF flow through the shunt and has substantially no pressure threshold to be overcome for the intracranial pressure. The check valve which hinders retrograde flow of blood from the sagittal sinus can e.g. be constructed as a silicone ball of the same mass weight as CSF, which is placed in a chamber 10 where the proximal, upstream inlet can be occluded by the ball, and where the distal, downstream end is kept open by ridges (6) around the orifice.

According to a preferred embodiment, the check valve comprises four guiding ridges (5) and four guiding and abutment 15 ridges (6) in the chamber of the check valve. The ridges (5, 6) extend parallel to the direction of flow of the liquid. The guide ridges (5) extend from the inlet side of the chamber of the check valve till approximately the middle of the chamber of the check valve where the guide and abutment 20 ridges (6) start and extend to the outlet side of the chamber. The ridges (6) serve to prevent the ball (4) of the check valve from reaching the outlet opening of the chamber of the check valve. The radial placing of the ridges (5, 6) can be directly recognized from Fig. 4.

25 The use of the sagittal sinus as a permanent reception site for CSF inherits a risk of complicating thrombosis of the sagittal sinus. Placing a permanent drain in the sagittal sinus has previously been used in attempts to treat hydrocephalus. A pressure regulating shunt system has been connected to a drain inserted in the sagittal sinus. The results 30 have been reported in two papers, including in total 70 patients (Hash et al. 1979; Wen, 1981). Thrombosis of the sinus was not seen in any of the reported cases. Hydrocephalus could be treated by this method, but because of the use 35 of a shunt type with in-built, predefined opening pressure

the shunts were only effective in cases with very high intracranial pressure.

The flow of blood in the sagittal sinus has been measured at MRI studies. The very high flow in the range above 400 ml/min probably hinder formation of thrombus around the drain or in the sinus. As a part of the present project, the effect of placing a drain in the sagittal sinus was analyzed in an animal investigation. In 5 dogs a silicone rubber catheter was placed in the sinus and observed for more than 3 weeks.

10 Examination of the drain, the walls of the sinus, and the sinus itself did not macroscopically or at histological examination show any sign of thrombosis or endothelial proliferation on the drain or in the sinus.

In a preferred embodiment of the cerebrospinal fluid shunt system, the internal radius ( $R$ ) of the tubular flow passage restricting means is less than about 0.20 mm and the flow-restricting part of the tubular flow passage restricting means has a length ( $L$ ) which is calculated according to the law of Hagen-Poiseulle taking into consideration the aim to provide a resistance to CSF-outflow through the shunt which is similar to the normal resistance, i.e. 8-12 mm Hg/ml/min such as about 10 mm Hg/ml/min. In particularly preferred embodiments, the internal radius ( $R$ ) of the tubular flow passage restricting means is e.g. about 0.10 mm, about 0.11 mm, about 0.12 mm, about 0.13 mm, about 0.14 mm, about 0.15 mm, about 0.16 mm, about 0.17 mm, about 0.18 mm or about 0.19 mm and the length ( $L$ ) is calculated accordingly.

As an example, the length ( $L$ ) can be calculated as follows:

30 
$$L = ((ICP - P_{ss}) * \pi * R^4) / (8 * F * V)$$
 Hagen-Poiseulle's law

wherein ICP is the intracranial pressure,  $P_{ss}$  is the pressure in the sagittal sinus,  $F$  is the flow rate of the cerebrospinal fluid and  $V$  is the viscosity of the cerebrospinal fluid. If  $ICP - P_{ss}$  is set to be 4 mm Hg,  $R$  is set to be 0.15 mm,  $F$

is set to be 0.3 ml/min and V is set to be 0.0072 dyn\*s/cm<sup>2</sup>, then for a Rout between 8 and 12 mm Hg/ml/min, the length is calculated to be between 1.77 cm and 2.65 cm. In a similar manner, the dimensions of various tubular flow passage restricting means can be calculated. It will be evident that various combinations of dimensions as illustrated in Fig. 10 are within the scope of the invention.

In the laboratories of Danish Technological Institute (DTI) the dimensioning has been tested in a test bench. The results 10 of the tests correspond to the calculated results for various dimensions. This means that it is possible to construct a shunt system that has the same resistance to outflow of CSF as the normal, "natural" CSF pathways possess. It should be noted that although the above formula can be used as a guidance, the results of the practical investigations have shown 15 that the relationship between the resistance to outflow of CSF (Rout) and the length of the tubular flow passage restricting means is not completely linear. For practical purposes, however, Hagen-Poiseulle's law can be used to calculate 20 appropriate dimensions of the tubular flow passage restricting means.

In general, the tubular flow passage restricting means will have a length within the range of 3.5 mm to 83.8 mm, preferably within the range of 17.7 mm to 26.5 mm, such as about 25 22.1 mm, either in itself or defined within said shunt main body. This length may be divided in two or more individual segments, if considered appropriate, as illustrated in Figs. 2 and 3.

#### BEST MODE FOR CARRYING OUT THE INVENTION

30 In a presently preferred embodiment, the shunt consists of a catheter for the ventricle, a body (Figs. 1 to 6) containing the resistance device and a ball valve substantially without any inherited resistance compared to the resistance in the

flow passage restricting means, and a drain to be introduced into the sagittal sinus.

The shunt is placed subcutaneously on the top of the calvarium, behind the coronal suture on the right (or left) side 5 of the sagittal suture. Via a burrhole a catheter is inserted in the right (or left) ventricle and connected to the body of the shunt. A small burrhole (2-3 mm) is placed directly over the sagittal sinus, running in the midline beneath the readily identifiable sagittal suture. A drain of the same outer 10 diameter as the burrhole is introduced into the sagittal sinus and connected to the "distal" end of the shunt. Figs. 8 and 9 show the principles of the location of the shunt device.

Suitable ventricular drains are well-known within the art and 15 can e.g. be a plain, 3 mm outer diameter silicone rubber drain. Standard produced drains may be preferred.

In a presently preferred embodiment, the shunt main body is constructed from a suitable material such as a silicone rubber and has preferably an antechamber with a perforable 20 dome. In the proximal ("the top") end the dome ends in a tip where the ventricular drain can be connected and secured. In the distal end of the dome the inlet to the flow regulator is placed.

The antechamber will generally have a flat bottom consisting 25 of hard silicone rubber. The dome is made of soft, perforable, self-healing silicone rubber. The ventricular drain is attached to the inlet connector, which is provided with a brim. The length of the connector is generally about 5 mm. The drain is secured the usual way e.g. by a ligature. The 30 antechamber is attached to the tubule containing the tubular flow passage restricting means.

The tubular flow passage restricting means is dimensioned according to Hagen-Poiseulle's law to a resistance to flow at

about 8-12 mm Hg/ml/min such as 10 mm Hg/ml/min. In a presently preferred embodiment the tubular flow passage restricting means has a length of about 22.1 mm which may be divided into two parts (see Figs. 2 and 3) and the internal radius of 5 the flow-restricting part of the device is 0.15 mm. The tubular flow passage restricting means is substantially straight and the walls are substantially smooth. The material of the tubular flow passage restricting means can be hard silicone rubber or HD polyethylene (e.g. gas sterilized polypropylene), polycarbonate, polysulfone, polystyrene or PVC. Alternatively, the tube can be of titanium.

The valve means may consist of a chamber into which the flow regulating tube ends in a bowl (Figs. 1-3 and 5-7). A ball made of a material with the same mass weight as CSF is placed 15 in the chamber. Examples of such material are polyethylene, polysulfone, polystyrene and glass with air inside. The distal end of the chamber leads to the tubule where the drain for the sagittal sinus is to be attached. In one embodiment, three ridges stop the ball from occluding the flow in the 20 direction of the sagittal sinus. Figs. 2-4 show an alternative embodiment wherein the housing is circular or oval and designed so that the ball is only supported by two ridges at a time, said ridges having sharp contours in order to avoid "adhesion".

25 Alternatively, the check valve could be placed at the inlet end of the flow regulating tube. As an example, the valve means may consist of said ball embodied in a chamber ending at the inlet end of the tube in sharp ridges. The opening into the antechamber may be circular, the edges of the hole 30 rigid, and the diameter of the hole smaller than the ball (Figs. 5-7).

The valve mechanism may be constructed with a flat back side (see Fig. 2). The outlet of the first flow-regulating tube may be provided with soft lips or have an excavation matching 35 the periphery of the ball.

Alternatively, the check valve means could be with guided rigid valve members, e.g. shaped as rings, or be with flexible valve members e.g. with tongue-shaped laminae.

The drain for the sagittal sinus may be made of e.g. titanium 5 tube or silicone rubber tube. The distal 5 mm of the tube will generally have an outer diameter of 2 mm and an inner diameter of 1.5 mm. The part of the drain that goes through the skull has generally an outer diameter of 3 mm, the inner diameter is 1.5 mm. The part of the drain with the largest 10 diameter may be shortened to fit the distance from the body of the shunt to the hole over the sagittal sinus.

Another design of the drain is to use a titanium tube with an inner diameter of 1.5 mm and a length of 20 mm. The tube is attached to a silicone rubber tube with outer/inner diameter 15 3/1.5 mm and of 60 mm length. The titanium tube is readily inserted via a 2 mm wide burrhole through the bone covering the sagittal sinus. A stilet in the tube allows the inserted tube to be angled somewhat to lead the silicone rubber tube following the surface of the skull to the body of the shunt.

## CLAIMS

1. A cerebrospinal fluid shunt system comprising  
5 brain ventricle catheter means for insertion into the brain  
ventricle so as to drain cerebrospinal fluid from said brain  
5 ventricle;

sinus sagittalis catheter means for insertion into the sinus  
sagittalis for feeding said cerebrospinal fluid into sinus  
sagittalis;

10 shunt main body means connected at one end thereof to said  
brain ventricle catheter means and at another end thereof to  
said sinus sagittalis catheter means for providing fluidic  
communication between said brain ventricle catheter means and  
said sinus sagittalis catheter means; and

15 tubular flow passage restricting means defined within said  
shunt main body defining a resistance to flow of 8-12 mm  
Hg/ml/min.

2. A cerebrospinal fluid shunt system according to claim 1  
wherein the resistance to flow is about 10 mm Hg/ml/min.

20 3. A cerebrospinal fluid shunt system according to claim 1 or  
2 having check valve means disposed within said shunt main  
body for preventing said cerebrospinal fluid from flowing  
back from said sinus sagittalis catheter to said brain ven-  
tricle catheter.

25 4. A cerebrospinal fluid shunt system according to any of  
claims 1-4 wherein the internal radius (R) of the tubular  
flow passage restricting means is about 0.20 mm or less.

Int. Application No  
PCT/DK 97/00392

**A. CLASSIFICATION OF SUBJECT MATTER**  
IPC 6 A61M27/00

According to International Patent Classification(IPC) or to both national classification and IPC

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)  
IPC 6 A61M

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	US 4 605 395 A (ROSE ET AL.) 12 August 1986 see abstract see column 1, line 35 - column 2, line 15; figures 2-5	1-4
A	US 4 781 674 A (REDMOND ET AL.) 1 November 1988 see abstract see column 1, line 57 - column 2, line 3; figures 1-7	1-4
A	US 3 566 875 A (STOEHR) 2 March 1971	
A	US 4 784 648 A (SINGH ET AL.) 15 November 1988	

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

\* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family
